How this works

Our Wellness Reports analyze how your DNA influences your health.
We then use this analysis to give you personalized risk estimates and recommendations.

Similarly, our Trait Reports look at how your DNA influences your traits.

Your DNA is like an instruction manual — it contains a lot of information.
You can think of it as a blueprint for your body.

Genetic variants are parts of DNA that differ from person to person. Some can make you more vulnerable to certain health issues, while others may influence traits such as eye color.

We use artificial intelligence and machine learning to analyze all this information.
We then summarize your results as a risk score or display it on a gauge.

In total, we analyze up to 83 million genetic variants.

When we give a risk score, the risk icon tells you if you are at a higher or lower risk compared to other people:

Genotype color info:

AA

You don't have any risk alleles

AA

You have 1 risk allele

AA

You have 2 risk alleles

Your risk is also displayed as a percentile. This will tell you how your risks compare to our sample population. The lower your percentile number, the lower your risk. The "50th percentile" would be an average risk.

Similarly, the gauge tells you your relative risk score compared to our sample population, or it indicates a specific trait or haplotype you are more likely to have based on your genetic variants.

When applicable, we also list top evidence-based recommendations that may help lower your risk. The focus is on recommendations that may be of benefit to you, based on your genetics.

Our recommendations come in four categories: lifestyle, diet, supplements and drugs. The following icons tell you which category a recommendation falls into:

Our team of scientists also ranks each recommendation.
We rank based on impact and the strength of evidence in the medical literature.

Impact shows how strongly a recommendation will affect your health in a certain area.
Evidence is how much scientific support there is for the recommendation. Rankings are from 1 to 5 (low to high):

Impact

Impact scores range from 1-5. These scores reflect how much of an effect each recommendation can have. An impact score of 5 predicts the biggest effect.

When a recommendation affects something we can measure, we use those measurements to assign the impact score. For example, a recommendation that decreases cholesterol by 20% will have a higher impact score than one that decreases it by 5%.

Some recommendations affect things that we cannot directly measure, like stress or mood. For these, the impact score is based on how well they work relative to other recommendations and standard treatments. The best ones get the highest scores.

If there is a lot of research that shows a recommendation works especially well for your genotype, the impact score gets increased.

Recommendation Evidence

- 5 / 5
- Recommendations that are considered effective and generally recommended by experts and medical bodies.
-
- 4 / 5
- Recommendations that are considered likely effective and that have multiple independent meta-analyses and a great many studies supporting them.
-
- 3 / 5
- Recommendations that are considered possibly effective and have many studies supporting them
-
- 2 / 5
- Recommendations that have insufficient evidence, with two or several clinical trials supporting them, or many studies but with ambiguous results.
-
- 1 / 5
- Recommendations that have insufficient evidence, with a single clinical trial, or with many studies most of which didn't find support for the recommendation.
-
- 0 / 5
- No evidence in humans.

Genotype-specific Evidence

- High-quality
- Direct evidence that a recommendation helps more in people with your gene variant (many clinical trials, a few large clinical trials, or a meta-analysis).
-
- Medium-quality
- Direct evidence that a recommendation helps more in people with your gene variant (a few clinical trials or one large clinical trial).
-
- Low-quality
- Direct evidence that a recommendation helps more in people with your gene variant (a single clinical trial or more trials with inconsistent results).
-
- Indirect
- A recommendation may help more in people with your gene variant because it targets a specific gene or protein affected by your variant (e.g., MTHFR, dopamine).
-
- In theory
- A recommendation may help more in people with your gene variant because it targets a specific mechanism affected by your variant (e.g., inflammation, oxidative stress).

Some things to keep in mind:

- Genetics doesn’t play a considerable role in a condition or a trait.
- There is not enough research available to estimate a genetic predisposition.
- There are technical limitations to estimating or presenting a genetic predisposition.
- The topic is sensitive, and a genetic predisposition should only be estimated and presented by a healthcare professional.

Introduction

The [GAD1](#) gene encodes the 67 kDa isoform of glutamic acid decarboxylase, an enzyme that breaks down the anxiety-inducing neurotransmitter glutamate into [GABA](#) (gamma-aminobutyric acid) in the brain [\[R\]](#), [\[R\]](#).

GABA is a neurotransmitter that plays an irreplaceable role in the brain and the nervous system. Brain cells that produce GABA are called GABAergic neurons and are distributed throughout the brain [\[R\]](#).

GABA is the main inhibitory neurotransmitter that prevents the over-stimulation of brain cells. An abnormal GABA activity can produce mental illness and symptoms such as [anxiety](#), depression, insomnia, convulsions, and epilepsy [\[R\]](#), [\[R\]](#).

GAD1 Genetics

The most well-researched *GAD1* polymorphism is [rs3749034](#). Its major ‘G’ allele has been shown to reduce GAD1 activity, resulting in lower GABA levels in the brain. In addition, this variant has been associated with an increased risk of [\[R\]](#):

- Schizophrenia [\[R, R, R\]](#)
- Hyperactive and impulsive symptoms in ADHD [\[R\]](#)

However, this variant has also been linked to lower odds of bipolar disorder and fewer respiratory symptoms in people with panic disorder [\[R, R\]](#).

Another variant associated with schizophrenia is the minor ‘A’ allele at [rs1978340](#). Surprisingly, this variant has been shown to reduce GABA levels. The fact that GABA acts as an inhibitory neurotransmitter in the mature brain but has the opposite activity during brain development may explain the complex effects of GABA levels on conditions such as schizophrenia and ADHD [\[R, R, R, R\]](#).

This variant has also been linked to:

- Cocaine dependence [\[R\]](#)
- Panic disorder and respiratory symptoms in this condition [\[R, R\]](#)
- Earlier onset of alcohol dependence [\[R\]](#)

However, this allele was associated with a reduced risk of heroin addiction [\[R\]](#).

WORSE

Likely worse GAD1 genetics based on the genetic variants we looked at

Your top variants that most likely impact your genetic predisposition:

GENE	SNP	GENOTYPE
GAD1	rs3749034	GG
GAD1	rs1978340	GA

The number of "risk" variants in this table doesn't necessarily reflect your overall result.

Next Steps

Remember, your genes only tell one important part of your health story!

Now that you've seen your DNA-based results for this health topic, let's take a look at other contributing factors.

Your lab results

Your lab results are impacted by the combined effect of your genes, environment and lifestyle.

Lab tests will give you the best picture of your current health status, while your genes provide insight into your health predispositions and which recommendations are best for you.
