WEIGHT

137lb 62kg

How this works

Our Wellness Reports analyze how your DNA influences your health.
We then use this analysis to give you personalized risk estimates and recommendations.

Similarly, our Trait Reports look at how your DNA influences your traits.

Your DNA is like an instruction manual — it contains a lot of information.
You can think of it as a blueprint for your body.

Genetic variants are parts of DNA that differ from person to person. Some can make you more vulnerable to certain health issues, while others may influence traits such as eye color.

We use artificial intelligence and machine learning to analyze all this information.
We then summarize your results as a risk score or display it on a gauge.

In total, we analyze up to 83 million genetic variants.

When we give a risk score, the risk icon tells you if you are at a higher or lower risk compared to other people:

Genotype color info:

AA

You don't have any risk alleles

AA

You have 1 risk allele

AA

You have 2 risk alleles

Your risk is also displayed as a percentile. This will tell you how your risks compare to our sample population. The lower your percentile number, the lower your risk. The "50th percentile" would be an average risk.

Similarly, the gauge tells you your relative risk score compared to our sample population, or it indicates a specific trait or haplotype you are more likely to have based on your genetic variants.

When applicable, we also list top evidence-based recommendations that may help lower your risk. The focus is on recommendations that may be of benefit to you, based on your genetics.

Our recommendations come in four categories: lifestyle, diet, supplements and drugs.
The following icons tell you which category a recommendation falls into:

Our team of scientists also ranks each recommendation.
We rank based on impact and the strength of evidence in the medical literature.

Impact shows how strongly a recommendation will affect your health in a certain area.
Evidence is how much scientific support there is for the recommendation. Rankings are from 1 to 5 (low to high):

Impact

Impact scores range from 1-5. These scores reflect how much of an effect each recommendation can have. An impact score of 5 predicts the biggest effect.

When a recommendation affects something we can measure, we use those measurements to assign the impact score. For example, a recommendation that decreases cholesterol by 20% will have a higher impact score than one that decreases it by 5%.

Some recommendations affect things that we cannot directly measure, like stress or mood. For these, the impact score is based on how well they work relative to other recommendations and standard treatments. The best ones get the highest scores.

If there is a lot of research that shows a recommendation works especially well for your genotype, the impact score gets increased.

Recommendation Evidence

- 5 / 5
- Recommendations that are considered effective and generally recommended by experts and medical bodies.
-
- 4 / 5
- Recommendations that are considered likely effective and that have multiple independent meta-analyses and a great many studies supporting them.
-
- 3 / 5
- Recommendations that are considered possibly effective and have many studies supporting them
-
- 2 / 5
- Recommendations that have insufficient evidence, with two or several clinical trials supporting them, or many studies but with ambiguous results.
-
- 1 / 5
- Recommendations that have insufficient evidence, with a single clinical trial, or with many studies most of which didn't find support for the recommendation.
-
- 0 / 5
- No evidence in humans.

Genotype-specific Evidence

- High-quality
- Direct evidence that a recommendation helps more in people with your gene variant (many clinical trials, a few large clinical trials, or a meta-analysis).
-
- Medium-quality
- Direct evidence that a recommendation helps more in people with your gene variant (a few clinical trials or one large clinical trial).
-
- Low-quality
- Direct evidence that a recommendation helps more in people with your gene variant (a single clinical trial or more trials with inconsistent results).
-
- Indirect
- A recommendation may help more in people with your gene variant because it targets a specific gene or protein affected by your variant (e.g., MTHFR, dopamine).
-
- In theory
- A recommendation may help more in people with your gene variant because it targets a specific mechanism affected by your variant (e.g., inflammation, oxidative stress).

Some things to keep in mind:

- Genetics doesn’t play a considerable role in a condition or a trait.
- There is not enough research available to estimate a genetic predisposition.
- There are technical limitations to estimating or presenting a genetic predisposition.
- The topic is sensitive, and a genetic predisposition should only be estimated and presented by a healthcare professional.

Introduction

The [SOAT1](#) gene, also known as sterol O-acyltransferase 1, plays an important role in cholesterol metabolism. The **ACAT-1** enzyme, encoded by SOAT1, is responsible for converting free cholesterol into cholesterol esters, which are stored in lipid droplets within cells.

This process is crucial for maintaining cellular cholesterol balance and is particularly active in the adrenal glands, where cholesterol esters are used for steroid hormone production. SOAT1 activity is also significant in macrophages, where it influences the formation of foam cells, a key step in the development of atherosclerosis.

Given its role in cholesterol homeostasis, SOAT1 has been studied in relation to cardiovascular diseases, metabolic disorders, and certain cancers. The gene is located on chromosome 1.

SOAT1 Genetics

The main *SOAT1* (ACAT-1) variant is [rs1044925](#). Its “C” allele is generally considered “bad” due to its link with higher SOAT1 activity, which may imply increased cholesterol buildup.

Studies have linked this variant to [\[R\]](#), [\[R\]](#), [\[R\]](#), [\[R\]](#):

- Higher cholesterol levels in men
- Higher blood pressure
- Alzheimer’s disease
- Chagas disease (tropical disease that may involve heart problems)

However, some studies didn’t find a link between this variant and blood lipids or Alzheimer’s. One study even found a protective effect on heart health due to higher HDL cholesterol levels [\[R\]](#), [\[R\]](#), [\[R\]](#), [\[R\]](#).

Other SOAT1 variants include:

- [rs11545566](#)-G: A study linked it to heart disease and artery hardening [\[R\]](#)
- [rs2247071](#)-C: May be linked to Alzheimer’s disease [\[R\]](#)
- [rs13306731](#)-G: Studies have linked it to heart problems [\[R\]](#)

Lower SOAT1 (ACAT-1) activity means less conversion of free cholesterol to cholesterol esters. This reduces cholesterol storage in cells and may help prevent foam cell formation in arteries. It may also reduce the formation of amyloid plaques in the brain [\[R\]](#), [\[R\]](#).

LOWER ACTIVITY

Likely lower SOAT1 activity based on 4 genetic variants we looked at

Your top variants that most likely impact your genetic predisposition:

GENE	SNP	GENOTYPE
AXDND1	rs11545566	GG
TOR3A	rs2247071	CC
AXDND1	rs1044925	AA
SOAT1	rs13306731	AA

The number of "risk" variants in this table doesn't necessarily reflect your overall result.
