

# VWF (Bleeding Disorders)

## Gene Report

REPORT CATEGORY —

Sample Client

Report date: 15 January 2026

# Table of Contents

## 03 How this works

- 04 Impact
- 05 Evidence
- 06 Some things to keep in mind

## 07 Introduction

## 08 Your genetics

DISCLAIMER

This report does not diagnose this or any other health conditions. Please talk to a healthcare professional if this condition runs in your family, you think you might have this condition, or you have any concerns about your results.

# Personal information

NAME

Sample Client

SEX AT BIRTH

Male

HEIGHT

5ft 5" 165cm

WEIGHT

137lb 62kg

# How this works

Our Wellness Reports analyze how your DNA influences your health.  
We then use this analysis to give you personalized risk estimates and recommendations.

Similarly, our Trait Reports look at how your DNA influences your traits.

Your DNA is like an instruction manual — it contains a lot of information.  
You can think of it as a blueprint for your body.

Genetic variants are parts of DNA that differ from person to person. Some can make you more vulnerable to certain health issues, while others may influence traits such as eye color.

We use artificial intelligence and machine learning to analyze all this information.  
We then summarize your results as a risk score or display it on a gauge.

In total, we analyze up to 83 million genetic variants.

When we give a risk score, the risk icon tells you if you are at a higher or lower risk compared to other people:

Genotype color info:

AA

You don't have any risk alleles

AA

You have 1 risk allele

AA

You have 2 risk alleles

Your risk is also displayed as a percentile. This will tell you how your risks compare to our sample population. The lower your percentile number, the lower your risk. The "50th percentile" would be an average risk.

Similarly, the gauge tells you your relative risk score compared to our sample population, or it indicates a specific trait or haplotype you are more likely to have based on your genetic variants.

When applicable, we also list top evidence-based recommendations that may help lower your risk. The focus is on recommendations that may be of benefit to you, based on your genetics.

Our recommendations come in four categories: lifestyle, diet, supplements and drugs. The following icons tell you which category a recommendation falls into:

Our team of scientists also ranks each recommendation.  
We rank based on impact and the strength of evidence in the medical literature.

Impact shows how strongly a recommendation will affect your health in a certain area.  
Evidence is how much scientific support there is for the recommendation. Rankings are from 1 to 5 (low to high):

# Impact

Impact scores range from 1-5. These scores reflect how much of an effect each recommendation can have. An impact score of 5 predicts the biggest effect.

When a recommendation affects something we can measure, we use those measurements to assign the impact score. For example, a recommendation that decreases cholesterol by 20% will have a higher impact score than one that decreases it by 5%.

Some recommendations affect things that we cannot directly measure, like stress or mood. For these, the impact score is based on how well they work relative to other recommendations and standard treatments. The best ones get the highest scores.

If there is a lot of research that shows a recommendation works especially well for your genotype, the impact score gets increased.

## Recommendation Evidence

5 / 5

Recommendations that are considered effective and generally recommended by experts and medical bodies.

4 / 5

Recommendations that are considered likely effective and that have multiple independent meta-analyses and a great many studies supporting them.

3 / 5

Recommendations that are considered possibly effective and have many studies supporting them

2 / 5

Recommendations that have insufficient evidence, with two or several clinical trials supporting them, or many studies but with ambiguous results.

1 / 5

Recommendations that have insufficient evidence, with a single clinical trial, or with many studies most of which didn't find support for the recommendation.

0 / 5

No evidence in humans.

## Genotype-specific Evidence

High-quality

Direct evidence that a recommendation helps more in people with your gene variant (many clinical trials, a few large clinical trials, or a meta-analysis).

Medium-quality

Direct evidence that a recommendation helps more in people with your gene variant (a few clinical trials or one large clinical trial).

Low-quality

Direct evidence that a recommendation helps more in people with your gene variant (a single clinical trial or more trials with inconsistent results).

Indirect

A recommendation may help more in people with your gene variant because it targets a specific gene or protein affected by your variant (e.g., MTHFR, dopamine).

In theory

A recommendation may help more in people with your gene variant because it targets a specific mechanism affected by your variant (e.g., inflammation, oxidative stress).

## Some things to keep in mind:

- Genetics doesn’t play a considerable role in a condition or a trait.
- There is not enough research available to estimate a genetic predisposition.
- There are technical limitations to estimating or presenting a genetic predisposition.
- The topic is sensitive, and a genetic predisposition should only be estimated and presented by a healthcare professional.

# Introduction

The [VWF](#) gene encodes Von Willebrand Antigen or Von Willebrand Factor (VWF), a protein found in blood plasma that plays a critical role in the process of blood clotting. It is named after Dr. Erik von Willebrand, who first described the bleeding disorder associated with its deficiency, known as von Willebrand disease (VWD) [\[R\]](#).

VWF acts by binding to clotting factors and platelets, facilitating the formation of a platelet plug at sites of vascular injury. This process is essential for stopping bleeding and ensuring normal wound healing [\[R\]](#).

A deficiency in VWF can lead to excessive bleeding and difficulty in blood clotting, characteristic of von Willebrand disease, the most common inherited bleeding disorder. On the other hand, elevated levels may be associated with an increased risk of thrombosis, where blood clots form inappropriately within blood vessels, leading to conditions like deep vein thrombosis or stroke [\[R, R\]](#).

# VWF Genetics

Von Willebrand disease is a bleeding disorder with slow blood clotting and abnormal bleeding. People with this condition often experience [\[R\]](#):

- Easy bruising
- Excessive bleeding or oozing after injuries, surgery, or dental work
- Long-lasting nosebleeds
- Heavy or long periods
- Heavy bleeding during labor

Von Willebrand disease is caused by mutations leading to the production of lower VWF protein levels (type 1), aberrant forms of the protein with impaired function (type 2), or total lack of the protein (type 3). Most cases are inherited in an autosomal dominant pattern, which means only one copy of the mutated allele is sufficient to cause the disorder. Some of the variants associated with this condition include [\[R\]](#), [\[R\]](#):

- ‘C’ of [rs1800386](#)
- ‘A’ of [rs121964894](#)
- ‘C’ of [rs267607353](#)
- ‘T’ of [rs41276738](#)

TYPICAL ACTIVITY

Predisposed to typical VWF activity based on the genetic variants we looked at

Your top variants that most likely impact your genetic predisposition:

| GENE | SNP         | GENOTYPE |
|------|-------------|----------|
| VWF  | rs41276738  | CC       |
| /    | rs267607353 | AA       |
| VWF  | rs1800386   | TT       |

The number of "risk" variants in this table doesn't necessarily reflect your overall result.
